INTRODUCTORY LETTER.

WASHINGTON, May 17, 1858.

PROFESSOR JOSEPH HENRY, LL.D.,

Secretary of the Smithsonian Institution:

DEAR SIR: The records of the magnetic observations made under the direction of Dr. Kane, in the second expedition to the Arctic regions, were placed in my hands by his late lamented father, Judge Kane, in December last.

Dr. Kane had selected Assistant Charles A. Schott, of the Coast Survey, for the reduction of a considerable portion of the observations made in that expedition; and I, therefore, placed these in Mr. Schott's possession for reduction and discussion. The work has been faithfully performed, and I recommend it for publication in the "Smithsonian Contributions to Knowledge." It is proper to state that the instruments were furnished by the Coast Survey and the Smithsonian Institution, and that the computations have been made at the expense of the latter.

Very respectfully, yours,

A. D. BACHE.

SECTION I.

MAGNETIC DECLINATION.

1854.

COMMENTS AND ADJUSTMENTS.

Instruments.—The observations for diurnal inequality as well as those for absolute declination, were made with a Jones unifilar magnetometer (No. 3), kindly loaned by Prof. A. D. Bache, Superintendent U. S. Coast Survey. The azimuth circle reads to $20''$ and the centre division of the scale reads 280. The magnet was suspended by means of a silk thread $9\frac{1}{2}$ inches in length. Several trials to determine the effect of torsion gave such small quantities that it was not considered necessary to take the same into account. The instrument was not originally intended to give absolute declinations, but at the Winter Quarters the observer succeeded in obtaining a few values for absolute declination by detaching the box, containing the magnet, from the circle which bears the telescope. The same was then moved in azimuth until a well defined object within the small range of its vertical motion could be observed. The focus of the telescope was adjusted to the distance. We find the instrument "perched on a pedestal of frozen gravel," the contents of two barrels. This mounting was considered as stable as the rock underneath. On the 9th of June, 1854, Mr. Sonntag examined the instrument in reference to local disturbance, and found no sensible deviation arising from such a source. "The local deviation seems to have corrected itself; the iron in our comfortless little cell seems to have been so distributed that our results were not affected by it." (Narrative, vol. I.) The adjustments were made according to Riddel's magnetical instructions. The mirror attached to the suspended magnet faces the magnetic north. The following are the determinations for the angular value of a scale division:—

Circle.	Scale.	Circle.	Scale.	
Readings; January 13, 1854.			Winter Quarters, Van Rensselaer Harbor.	
120° 60'-58'	45 ^d .5	118° 11'-07'	253 ^d .0	
120 16—14	100.7	117 34—30	303.0	
120 16—14	92.5	117 34—30	303.2	
119 30—27	153.5	116 49—46	351.0	
119 30—27	148.0	116 49—46	354.5	
118 48—45	199.0	116 13—10	394.0	
118 48—45	201.0	116 05—00	405.5	
118 11—07	250.5	115 31—29	451.0	
				Taking alternate means, we obtain from each set the values:— $1^d = 0'.797.$

MAGNETIC DECLINATION.

Circle.	Scale.	Circle.	Scale.	
Readings; January 16, 1854.				(Dr. Hayes, observer.)
119° 31'-31'	452 ^d	121° 53'-55'	256 ^d	$1^d = 0'.741.$
120 48—46	350	123 19—18	150	
120 48—46	353	123 19—18	149	
122 09—06	251	124 42—40	42	
Readings; February 16, 1854.				
127° 04'-04'	62 ^d .5	121° 34'-34'	453 ^d .0	$1^d = 0'.839.$
125 55—56	153.0	122 55—56	356.0	
125 55—56	136.0	122 55—56	360.0	
124 18—17	257.0	124 23—24	249.0	
124 18—17	259.7	124 23—24	254.0	
123 00—00	355.0	125 47—47	150.0	
123 00—00	354.5	125 47—47	145.5	
121 34—34	463.0	127 05—05	42.0	
Value resulting, equal mean of all or one division of scale = 0'.804. Value adopted = 0'.80.				
An $\left\{ \begin{array}{l} \text{increase} \\ \text{decrease} \end{array} \right\}$ of scale readings indicates a movement of the north end of the magnet to the $\left\{ \begin{array}{l} \text{east} \\ \text{west} \end{array} \right\}$.				

A well rated pocket chronometer, nearly showing Greenwich mean time, was used for noting the time.

Diurnal Variation.—The observations for changes of magnetic declination were made during the months of January, February, and March, 1854, at the following dates:—

January 10-11	.	.	.	and	.	.	.	February 10-11
" 13-14	.	.	.	"	.	.	.	" 14-15
" 24-25	.	.	.	"	.	.	.	" 17-18
" 27-28	.	.	.	"	.	.	.	" 21-22
" 31-32	.	.	.	"	.	.	.	" 28-29
February 3-4	.	.	.	"	.	.	.	March 3-4
" 7-8	.	.	.	"	.	.	.	" 7-8

To these must be added the term days during the same period of the year, viz: January 18-19, February 24-25, and March 22-23. The remaining three terms in April, May, and June, of the same year, furnish values of the change of the diurnal inequality at a later season. Readings (the mean of two extremes during a vibration when the magnet was in motion) were taken every sixth minute, commencing, with but one exception, between 4 and 5 o'clock in the afternoon. The error of the chronometer has been applied and the time in the abstracts is given in local mean (astronomical) time. The readings are, as stated above, uncorrected for torsion, and are expressed in scale divisions. In regard to the observers, Dr. Kane remarks in his narrative: "It was not until the close of the winter that I was able to take my share in the preceding (the observations for variation) or the term-day observations; and I desire to express my obligations to Dr. Hayes and

Mr. Bonsal, as well as to George Stephenson, for their zealous and intelligent co-operation with Mr. Sonntag and myself." Each set of observations extends over twenty-four hours; they were taken nearly one minute earlier (between 56° and 40°) than indicated in the abstract. The general remark on page 435 of the second volume of the Narrative, "the scale reading 280 corresponds to a magnetic declination of $108^{\circ} 3'$ west, etc.," appears to leave no doubt that the instrument was left undisturbed, and there being no statement to the contrary, we can assume the hourly and daily means at the several days of observation to refer to the same zero or to be comparable amongst themselves. At a later period in June, 1854, the azimuth circle appears to have turned about 19 minutes.

Term-day Observations.—There were six in number. The observations commence at 10 P. M., mean Göttingen time, or about $4^{\text{h}} 37^{\text{m}} 34^{\text{s}}$ mean Fern Rock time, the difference of longitude being assumed to equal $5^{\text{h}} 22^{\text{m}} 26^{\text{s}}$. The observations were not taken at the precise instant as indicated in the abstracts; the small deviation is noted at the head of each table.

Absolute Declination.—The expedition not being provided with a proper instrument, the magnetometer was temporarily converted into a declinometer by Mr. Sonntag, who determined the declination on June 9th, the 14th, and the 26th, 1854. The top of a mountain was used as a mark; it bore south 22° west (magnetic).

The mirror attached to the magnets can be inverted so that the mean reading of mirror direct and mirror reversed corresponds to the reading of the magnetic axis of the magnet.

Geographical Position of Observatory.—The latitude and longitude of the astronomical observatory has been determined as follows: Lat. $78^{\circ} 37'.0$ north, Long. $70^{\circ} 40'$ west of Greenwich. (See p. 305, vol. II. of the Narrative, also pp. 385 and 387 of the same volume.) The island (Observatory Island) on which the observatory (Fern Rock Observatory) was placed, was some fifty paces long by perhaps forty broad. (See p. 116, vol. I. of Narrative.) The magnetic observatory was adjoining; it was of stone, ten feet square, with a wooden floor as well as roof, and supplied with a copper fire grate. No iron was used in its construction.

The following is an extract of note 56, p. 464, of vol. I. of the Narrative: "The subjoined are given as aids to physical inquiry on the part of future travellers: Directions to sites of Rensselaer harbor. The observatory was placed upon the northernmost of the rocky group of islets that formed our harbor. It is seventy-six English feet from the highest and northernmost salient point of this island, in a direction S. 14° E., or in one with said point and the S. E. projection of the southernmost islet of the group. A natural face of gneiss rock formed the western wall of the observatory. A crevice in this rock has been filled with melted lead, in the centre of which is a copper bolt. Eight feet from this bolt, and in the direction indicated by the crevice, stood the magnetometer. This direction is given in case of local disturbance from the nature of the surrounding rocks."

The highest point of the island was about thirty feet above the mean tide level of the harbor. The observatory was known by the name of "Fern Rock Observatory."

7	389	379	373	371	370	370	370	371	371		8	(373.5)
											Mean	358.6

Value of a division of the scale 0'.80.

Increase in scale readings corresponds to a movement of the north end of the magnet to the east.

NOTE.—Another stove had been put up temporarily; it was removed at the close of the observations.

AT VAN RENNSLAER HARBOR.

											Mean	274.5

Value of a scale division 0'.80.

Increase of scale readings corresponds to a movement of the north end of the magnet to the east.

NOTE.—The mean in brackets includes two interpolated values.

Diurnal Range of the Declination.—The diurnal range being an index to the magnitude of the diurnal excursions, is best presented before the examination of the diurnal inequality. The following table contains the highest and lowest scale readings in the hourly series, and the maximum and minimum values observed, together with the corresponding ranges. One division of scale = $0'.80$.

DAILY RANGE OF THE DECLINATION.

DATE.	IN HOURLY SERIES.		OBSERVED.		RANGE.	
	Highest.	Lowest.	Maximum.	Minimum.	In hourly series.	Total observed.

The mean diurnal total range observed during the above period becomes $2^{\circ} 28'.6$, and the maximum diurnal range observed took place on the 14-15 February, and amounted to $4^{\circ} 52'.0$. For comparison with similar quantities at other high latitude stations we may take Lake Athabasca, where the greatest range in any one day between October, 1843, and February, 1844, was $2^{\circ} 35'$, it happened October 16, 1843; at Fort Simpson the maximum range was $7^{\circ} 27'$, observed on the 16th of April, 1844, in a series of observations extending over April and May, 1844. The mean diurnal range during January and February, 1844, at Lake Athabasca, was $31'.4$, and the mean range at Fort Simpson in April and May of that year was $1^{\circ} 12'$, these two quantities, however, were taken from the hourly series.

If we classify the ranges according to this magnitude we obtain the following results:—

Daily range less than	1°	1
" " between	1 and 2°	6
" " "	2 and 3	4
" " "	3 and 4	3
" " "	4 and 5	3
" " greater than	5	0

The diurnal range in the winter months, January, February, and March, when compared with its annual fluctuation, is probably below the mean value of the year.

Diurnal Inequality of the Declination.—The following table contains the hourly means of all observations at the Winter quarters, between January 10 and March 23, 1854. The remaining observations on term-days at a later season have been excluded on account of their isolation. The above period includes the coldest season of the year, and during more than one-half of the period the sun was below the horizon.

The hourly means were made out separately for each month, the general mean includes seventeen values for each of the twenty-four hours. In January we have complete observations on six days, in February on seven, and in March on four days. The table also contains the monthly means, and all numbers are expressed in scale divisions (one division = $0'.80$).

ABSTRACT OF HOURLY MEANS DURING THE MONTHS OF JANUARY, FEBRUARY, AND MARCH, 1854, OBSERVED
AT FERN ROCK MAGNETIC OBSERVATORY.

(The readings are given in scale divisions; the values taken from the term-day observations embrace the same number of single readings between the same times.)

The values in the above table do not refer exactly to the even hour but to 3^m later.

Figures between brackets () are means derived from less than ten readings.

* These four values were observed on the 4th at the hours indicated.

CHANGES OF THE MAGNETIC DECLINATION

MEAN MONTHLY CURVES OF THE DIURNAL CHANGES OF THE MAGNETIC DECLINATION AT VAN
RENSSELAER HARBOR, 1854.

AND SIMULTANEOUS MEAN DIURNAL VARIATION AT GREENWICH.

The irregularities in the daily curves compared on succeeding days are very considerable, as may be seen by glancing the eye over the last column of the preceding table, headed "daily means." No observations on account of disturbances have been excluded from the table, and the following mean diurnal inequality, therefore, contains their full effect. Comparing each hourly mean in the last horizontal line of the above table with the general mean, the following figures represent the resulting diurnal inequality of the declination during the first three months of the year 1854. For the sake of comparison the diurnal inequality observed at Greenwich during the same seventeen days has been made out and is given in the last column.

MEAN DIURNAL INEQUALITY OF DECLINATION DURING SEVENTEEN DAYS IN JANUARY, FEBRUARY, AND MARCH, 1854, AT VAN RENSSLAER HARBOR, AND AT GREENWICH DURING THE SAME DAYS; EXPRESSED IN MINUTES OF ARC.

Local mean time.	Van Rensselaer.	Green-wich.	Local mean time.	Van Rensselaer.	Green-wich.	Local mean time.	Van Rensselaer.	Green-wich.	Local mean time.	Van Rensselaer.	Green-wich.

10	-21.0	-5.1	16	-27.8	+0.5	22	+30.6	+2.3	4	+7.0	+2.6

A negative sign indicates a deflection to the east, a positive one a deflection to the west of the mean position.

The diurnal inequality at the two stations presents in general the same characteristic features, namely, the principal deflection to the west shortly after noon, and the opposite eastern position about midnight; in regard to the diurnal inequality, therefore, the motion of the magnet at Van Rensselaer Harbor follows in general the same law as recognized in lower geographical latitudes.

The extreme westerly position is attained at noon; after this hour the westerly declination diminishes gradually, with an exception of a period of opposite motion of very limited range between the hours of four and five. The easterly extreme is reached two hours after midnight. Whether the small irregularity just noticed, producing apparently a secondary minimum and maximum, is real or only caused by the accidental deviations of the few observations under discussion, it is not easy to decide with certainty. The motion from 14 hours to 24 hours is performed with great uniformity. Thus, while the diurnal motion agrees with that observed at Lake Athabasca, Fort Simpson, Sitka, Toronto, etc., it shows no trace of that marked deviation observed at Reikiavik, in Iceland, or at Fort Confidence. In 1824 (June), at the Whalefish islands the maximum westerly deviation happened about a quarter past one o'clock P. M.; the time of the maximum eastern deflection was not determined. At Port Bowen the maximum westerly variation appears to have occurred between the hours of 10 A. M. and 1 P. M., the mean result being 11^h 49^m; the greatest deflection of the north end of the needle to the eastward took place between 8 P. M. and 2 A. M., the mean hour being 10 P. M. These observations were made during January, February, March, and April, 1825.

The range of the mean diurnal inequality is 1° 06'.8, when it is at Greenwich during the same time 10'.9.

Analysis of Disturbances of the Declination.—The declination at the commencement and end of the observations appears to have remained nearly the same; the daily and monthly means indicate at first a gradual decrease of westerly declination, which motion, however, is speedily overcome in the month of March. No further attention need be paid to this circumstance in the following discussion of the disturbances, and of their effect upon the diurnal inequality.

The mean disturbance for each of the 24 hours has been obtained by comparing the monthly mean with each hourly reading; let Δ equal this difference, n the

number of hourly readings (equal to 17), and m the mean disturbance, then $m = \pm \sqrt{\frac{\sum \Delta^2}{n-1}}$. This quantity is analogous to the mean error of an observation. In the following comparisons we must always bear in mind that the observations for the present discussion are rather limited, and that the comparisons with results at Lake Athabasca and Fort Simpson are of a date nearly ten years earlier. This interval is perhaps favorable to the comparison.

At Van Rensselaer Harbor the mean disturbance force is greater than at either place just named, and pretty regular during two well-marked periods, as shown by the following table:—

TABLE OF THE MEAN DISTURBANCE OF THE DECLINATION AT VAN RENSSLAER HARBOR, TAKEN WITHOUT REGARD TO DIRECTION, FOR EACH OF THE OBSERVATION HOURS, AND EXPRESSED IN MINUTES OF ARC.

Local Mean Time.

5h.	6h.	7h.	8h.	9h.	10h.	11h.	Midn.	13h.	14h.	15h.	16h.
$\pm 31'$	41	37	47	49	50	46	52	51	47	50	$\pm 53'$
<hr/>											
17h.	18h.	19h.	20h.	21h.	22h.	23h.	Noon.	1h.	2h.	3h.	4h.
$\pm 49'$	42	54	48	46	31	46	60 ¹	46	39	45	$\pm 41'$

The disturbing force is least during the day (if such an expression is admissible in this case), from 10 A. M. to 7 P. M., and greater and equally regular during the hours of the night (?), from 8 P. M. to 8 or 9 A. M. At Lake Athabasca the hours of least disturbance are between 9 A. M. and 7 P. M., and at Fort Simpson from 10 A. M. to 7 P. M. Captain Lefroy, in his discussion of the disturbances of the declination remarks: "There are indications in each of the three curves (for Lake Athabasca, Toronto and Sitka) of a small increase in the mean disturbance about noon." At Van Rensselaer Harbor we find the maximum disturbance at this very hour preceded and followed by quite small values; this circumstance certainly deserves our particular attention. Further coincidences of the disturbing force can be noticed at 5 P. M., at which hour at Van Rensselaer, Lake Athabasca, and Sitka the minimum disturbance has been observed. At Fort Simpson, in April and May, 1844, the mean disturbance was but one-fourth of that observed in January, February and March at Van Rensselaer, and the ratio of the minimum to the maximum value was 5.6 and 2.0 at the two places respectively.

By adding the squares of the differences for each hour of the day and month, we find the mean monthly disturbance by the formula $\sqrt{\frac{[\sum \Delta^2]}{N-24}}$. The mean disturbance for each month is as follows:—

In January, 1854	$\pm 30'$
In February, "	± 65
In March, "	± 40

¹ Principally due to a very large disturbance.

The month of February was, therefore, that of the maximum amount of disturbance. At Lake Athabasca the greatest mean disturbance occurred in January (from observations between October and February inclusive). At Toronto,¹ on the contrary, the months of January and June are those of least disturbance. It is quite possible that at Van Rensselaer the above values are surpassed in other months of the year, yet relatively February contains the greatest mean disturbance during the period of observations.

Hitherto the recognition and separation of the disturbed observations have been effected by an arbitrary process of fixing upon a certain deviation from the mean as the greatest allowable departure, and regarding all observations beyond this limit as disturbances. In the present case, I have sought to introduce a more definite idea by the application of Pierce's criterion for the rejection of doubtful observations,² or what is equivalent—for the recognition of the disturbances—they following a different law from the general one. The average mean deviation of the readings composing an hourly mean I find = $\pm 46'$, and for 17 values $x^2 = 4.55$; hence readings deviating from the mean more than $1^\circ 38'$ or $123d$ are to be recognized as disturbances.

The table of hourly readings contains 23 such values, or one disturbed observation for every 18 ordinary readings. In the five years of hourly observations ending June 30, 1848, at Toronto, the disturbances averaged one in 17 of the whole body. Excluding the above 23 values from the mean, the diurnal inequality freed of the disturbances undergoes no material change, as shown by the following table:—

5h.	6h.	7h.	8h.	9h.	10h.	11h.	Midn.	13h.	14h.	15h.	16h.
+23'.7	+6.0	-3.8	-9.3	-16.4	-12.5	-22.5	-34.7	-27.3	-35.1	-34.1	-26'.0
17h.	18h.	19h.	20h.	21h.	22h.	23h.	Noon.	1h.	2h.	3h.	4h.
-20'.1	-8.0	+9.0	+19.0	+23.3	+30.0	+29.0	+29.2	+34.4	+25.7	+13.6	+6'.9

The maximum west deflection is displaced from noon to one o'clock. The general mean changed from 317.3^d to 316.5^d , and the range of the mean inequality from $1^\circ 06'.8$ to $1^\circ 09'.5$. Eleven deflections were towards the east and twelve towards the west. The limited number of observations renders it necessary to conclude the foregoing examination of the disturbances.

Aurora Borealis.—In connection with the disturbances, a short notice of the auroral displays witnessed at the winter quarters will here find an appropriate place. In conformity with the supposed periodicity of this phenomenon, as recognized by Prof. Olmstead, no brilliant and complete auroras have been seen; with an exception of a very few, they may all be placed in his fourth class, to which the most simple forms of appearances have been referred. The aurora of October 24, 1854,

¹ See Vol. III. of the Magnetical and Meteorological Observations at Toronto, Canada. Discussion by Major-General E. Sabine. London, 1857.

² See Gould's Astronomical Journal, Nos. 45 and 83.

at 9 P. M. (see first volume of the Narrative), appears to have been one of the more conspicuous displays. A full record of the rest will be found in the 8th volume of the Smithsonian Contributions to Knowledge, in the collection made by Peter Force, Esq. There are 19 in number. The following statement is given in a foot-note: "The processes have no apparent connection with the magnetic dip, and in *no* case did the needle of our unifilar indicate disturbance."

Term-day Observations for Change of Magnetic Declination.—These observations were made at the following dates: January 18–19, February 24–25, March 22–23, April 19–20, May 26–27, and June 21–22, 1854. The readings are given in the following tables:—

Value of a division of the scale 0'.80.

Increase of scale readings denotes a movement of the north end of the magnet to the east.

¹ This magnet I. 7 was undoubtedly used on all previous occasions. Mark reads on circle 338° 22', circle reads 314° 12'.

The results of the preceding tables have been thrown into curves, to which the corresponding readings at Greenwich and Washington have been added.¹ These readings have all been referred to the same scale, and thus present at a glance the great difference in the magnitude of the diurnal motion as well as that of the disturbances. The Greenwich observations were taken by means of photography; the Washington corresponding observations were also obtained by means of Brooke's automatic photographic registration, and have as yet only been published in the 6th volume of the Astronomical Expedition to Chili, under the direction of Lieut. Gilliss, U. S. N.; Washington, D. C., 1856.

For the Greenwich curves the zero line corresponds to 22° west declination. A remarkable absence of disturbances of any magnitude as well as a small diurnal range of motion at the time of the vernal equinox, is shown by the March curves both for Van Rensselaer and Greenwich.

There appear to be some disturbances common to both places, and if these indications should not be accidental they are of an opposite character, that is, a magnetic east deflection is presenting itself as a magnetic west deflection at the other station, and *vice versa*. For this the reader may examine hours 17 and 5½ of the curve for January 18 and 19, hours from 6 to 8, April 20th, and one or two other less striking cases. The needle at Van Rensselaer Harbor actually points with its north end to the south of the astronomical west, and its meridional component of the direction is pointing in a southern or opposite direction to the same component at Greenwich or Washington.

Absolute Declination.—The magnetic declination at Van Rensselaer Harbor was determined on three occasions in the summer of 1854. Two different magnets were used.

Determination of June 9th. Magnet A 68, mirror facing magnetic north.

W. at 1^h 31^m P. M.

Resulting mean declination (for June 16) 108° 22' W.; if we omit the 2d determination on account of disturbance, and apply a correction for diurnal change to the mean of the first and last determination, we find 108° 12' W.

SECTION II.

OBSERVATIONS OF THE MAGNETIC INCLINATION.

1853, 1854, AND 1855.

SECTION II.

MAGNETIC INCLINATION.

Instrument and Remarks.—The observations for dip were made by Mr. Sonntag by means of a Barrow dip circle received from Prof. Henry, of the Smithsonian Institution, through the courtesy of Col. Sabine. The inclinometer was supplied with Lloyd needles, for determining the total intensity, but unfortunately the complete record of these observations could not be recovered; the absence of the record for determining the constants necessary for their reduction being wanted, no use could be made of these observations, even for relative intensity at Saikatle and Marshall Bay, and the partial results given in Appendix XV., vol. II. of the Narrative, must, therefore, remain fruitless for the present. There is likewise a deficiency in the record of the dip observations at Van Rensselaer Harbor after February 23, 1854; the results, however, are all preserved in the Appendix just mentioned.

In regard to the index error of the dipping needles, we can only make an approximate comparison. The observations at New York, where the dip has been represented by the formula

$$I = 72^\circ.69 - 0.00491(t - 1845) + 0.00114(t - 1845)^2,$$

with a probable error of any single observation¹ of $\pm 3'.3$, would apparently produce a correction to needle 1 of $-9'$, and to needle 2 of $-14'$, the changes, however, from one station to another in the immediate vicinity of the city are much greater, and these quantities may, therefore, as well indicate local deviation as index error. The polarity of the needles has been reversed at each station, the effect of this operation upon the resulting dip is somewhat irregular, and will be found exhibited in tabular form.

¹ See Coast Survey Report of 1856, p. 240. The formula includes dip observations taken between December, 1822, and August, 1855 (exclusive of the observations of the present expedition).

MAGNETIC INCLINATION

STATION No. IX. NEAR MARSHALL BAY.

Latitude $78^{\circ} 52'$. Longitude $69^{\circ} 01'$.¹

The observations on September 3d, 1853, were made with the Lloyd needle, No. 1, Box B. The dip by the statical needle is $85^{\circ} 26'$, and the resulting corrected dip $84^{\circ} 49'$. See Narrative, vol. I. p. 99.

STATION No. X. VAN RENSSLAER HARBOR, WINTER QUARTERS. MAGNETIC OBSERVATORY ON FERN ROCK.

Latitude $78^{\circ} 37'$. Longitude $70^{\circ} 40'$. W. of G.

The resulting dip at Van Rensselaer Harbor may be taken as corresponding in time to June, 1854.

SECTION III.

OBSERVATIONS OF MAGNETIC INTENSITY.

1854 AND 1855.

SECTION III.

OBSERVATIONS AND DISCUSSION OF THE MAGNETIC INTENSITY.

THE instrument used (a unifilar magnetometer) has already been described. For the determination of the intensity, the long magnet A. 67 has exclusively been used for oscillations and deflections. The effect of the torsion in the suspension was found so small that it was neglected. The vibrations have been observed in sets of two, one containing the readings of the chronometer when the magnet was moving in the direction of the scale readings, and the other when the magnet was moving in the opposite direction.¹ A mean time pocket chronometer was generally used for noting the time, and its rate was too small to affect sensibly the duration of a single vibration. In the deflections, the magnets were always kept at right angles to one another; the distance of the middle of the deflecting magnet, A. 67, from the suspended magnet, is given by a scale divided into feet and decimals of a foot.² The observations were made by Mr. A. Sonntag. At Van Rensselaer Harbor the observations extend over the time from January, 1854, to May, 1855. Two other stations were occupied, one in June, 1855, at Hakluyt Island, the other in July, on the coast between Parker Snow Point and Cape York, at the return of the party.

The necessary constants have been determined at Washington, D. C.

Magnet A. 67 is nearly three inches in length, the two other magnets, I. 7 and I. 10, are somewhat shorter.

¹ The vibrations given in the Narrative, vol. II., Appendix, No. XV., pp. 431—434, are, therefore, double vibrations, and should have been noted as such.

² By some inadvertence, Appendix No. XV. of vol. II. of the Narrative contains the distances expressed in inches; it should have been given in feet and decimals, thus, 13 inches should be 1.3 feet, and 9 inches should read 0.9 feet.

January 17, 1854. Fern Rock Observatory, Van Rensselaer Harbor.

The detail record of the observations of deflections and vibrations at Van Rensselaer Harbor, in May, 1855, and of the vibrations at Hakluyt Island, and near Cape York, in June and July, 1855, could not be found; the results, however, are preserved in Appendix No. XV. of the Narrative (vol. II.), and are here-with subjoined.

DETERMINATION OF THE MOMENT OF INERTIA OF MAGNET A. 67.

(With stirrup and mirror attached.)

No determination of the moment of inertia of magnet A. 67 having been made by the expedition, it became necessary to determine the same afterwards. The following observations for this purpose were made by myself at the Coast Survey Office, Washington, D. C.

After adjusting the instrument and suspending A. 67, the following experiments of vibrations were made:—

March 18, 1858.		Mean time chronometer Kessels 1285.			
No. of vibrations.	Mean local time by chronometer 1285.	20 vibrations.	No. of vibrations.	Time by chronometer 1285.	18 vibrations.
0	9 ^h 31 ^m 10 ^s .7		0	10 ^h 28 ^m 51 ^s .3	
20	32 32.4	1 ^m 21 ^s .7	18	30 04.5	1 ^m 13 ^s .2
40	33 54.0	21.6	36	31 18.0	13.5
60	35 15.1	21.1	54	32 31.0	13.0
80	36 36.5	21.4	72	33 44.8	13.8
100	37 58.0	21.5	90	34 57.9	13.1
		Mean 1 21.47			Mean 1 13.32
Temp. 71°.8. (Rate of chronometer too small to affect the result.)			Arc 234 ^d and 328 ^d		Temp. 71°.0.
1 vibration=4 ^s .073.			242	318	1 vibration=4 ^s .073

The mirror was below the magnet in these two sets; in the following four sets it was above.

Magnet suspended with inertia ring Z , of the following dimensions: Outer diameter 2.322 inches; inner diameter 1.837 inches; thickness 0.188 inches at 69°; weight 648.937 grains: hence $K_1 = \frac{1}{2} (r^2 + r_1^2) w = 4.936$ (in feet and grains), $lg K_1 = 0.69338$.

RECAPITULATION OF RESULTS.						
March 18, 1858.			1 vibration, without ring . . .	4 ^s .073	—	Temp. 71°.8
" "			" " " . . .	4.073	—	" 71.0
" "			" with " . . .	—	7 ^s .294	" 75.0
" "			" " " . . .	—	7.301	" 75.0
" "			" without " . . .	4.071	—	" 76.0
" "			" " " . . .	4.063	—	" 76.0
March 19, 1858.			" " " . . .	4.061	—	" 75.0
" "			" with " . . .	—	7.301	" 75.0
Mean by combination . . .				T=4.069 at 74°.0	T ₁ =7.299 at 75°.0	

The moment of inertia of the magnet (with appendages) K becomes for the temp. 69° (and corrected for torsion)

$$K = K_1 \left(\frac{T^2}{T_1^2 - T^2} \right) = 2.220 \text{ and } \lg K = 0.34631.$$

Using 0.0000068 for the coefficient of dilatation for 1° Fahr., the above $\lg K$ for different temperatures becomes:

For 62°, $\lg K = 0.34628$ and $\lg \pi^2 K = 1.34058$

" 32, " 0.34609 " = 1.34039 (CHAS. A. S.)

The value of the induction coefficient

$$P = -\frac{r^2 r_1^5 \sin. u_1 - r_1^2 r^5 \sin. u}{r_1^5 \sin. u_1 - r^5 \sin. u}$$

may be put in the following convenient form—

$$P = -r^2 \frac{\sigma - \epsilon^5}{\sigma - \epsilon^5} \text{ where } \sigma = \frac{\sin. u^1}{\sin. u} \text{ and } \epsilon = \frac{r}{r_1}$$

We find:	June 7, 1854	$P = -0.007$
"	8, "	-0.003
"	8, "	-0.006
"	19, "	+0.009
"	19, "	-0.003
"	24, "	-0.001
"	24, "	{ +0.033 }
May 16, 1855	.	.	.	{ +0.035 }
"	17, "	{ +0.039 }
"	18, "	-0.011
"	19, "	-0.011

If we take the indiscriminate mean of the above values we find $P = +0.007$, and if we reject the three values marked by brackets, $P = -0.004$; the latter value is probably nearer the truth than the first one, but both are so small that they may be neglected in the computation of the intensity.

In the absence of observations, the temperature coefficient for the magnetic moment or q may be assumed = 0.0003, a value found for other magnets of the same magnetic moment and size; with but three exceptions, the temperature corrections are small.

After correcting for difference of temperature, the following results for magnetic moment m and horizontal intensity X have been computed by the formulae

$$\frac{m}{X} = \frac{1}{2} r^3 \sin. u \text{ and } m X = \frac{\pi^2 k}{T^2}.$$

66 MAGNETIC INTENSITY, FERN ROCK OBSERVATORY.

Mean value of $m = 0.330$ at $t = 36^\circ$.¹

RECAPITULATION OF VALUES OF X .

January 31, 1854	$X = 1.117$
February 20, "	1.117
June 15, "	1.121
May 18, 1855	1.203

Mean corresponding to June, 1854 1.139

Taking the above value 1.139 for the mean horizontal force during the whole period, and multiplying it by sec. $84^\circ 45' .8$, the total force at Van Rensselaer Harbor during the same period becomes $\phi = 12.479$.

By means of the known value of m the horizontal intensity at the stations Hakluyt Island and coast near Cape York has been computed as follows:—

Hakluyt Island, June 21, 1855 $X = 1.344$

Coast near Cape York, July 19, 1855 $X = 1.573$

¹ I redetermined m at Washington, D. C., in March, 1858, and found it equal to 0.311, exhibiting but a small loss of magnetism during nearly four years.
